What happens if you have high uric acid?

A state in which uric acid levels exceed 7.0 mg/dL is called "hyperuricemia." The higher the uric acid level and the longer the hyperuricemia lasts, the higher the risk of developing gout.

When the amount of uric acid in the blood increases too much, it sticks to the joint cartilage and the synovial membrane that protects the joints, crystallizing and gradually building up. When the excess uric acid is detached, white blood cells, which are immune cells, recognize it as a foreign body and attack it. At this time, the inflammatory substances released by the white blood cells cause severe pain and swelling.

Taking 10mg of Lutelinone derived from chrysanthemum flower extract per day for 12 weeks reduced serum uric acid levels by 6%
